## PRIORITY DOCUMENT

SUBMITTED OR TRANSMITTED IN  
COMPLIANCE WITH RULE 17.1(a) OR (b)

The Patent Office  
Concept House  
Cardiff Road  
Newport  
South Wales  
NP10 8QQ

REC'D 27 AUG 2004  
WIPO PC

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Signed *Stephen Horrell*  
Dated 20 August 2004

## Request for grant of a patent

(See the notes on the back of this form. You can also get an explanatory leaflet from the Patent Office to help you fill in this form)

1. Your reference PA 554

2. Patent application number  
(The Patent Office will fill in this part)

0402641.5

- 6 FEB 2004

3. Full name, address and postcode of the or of each applicant (underline all surnames)

CELLTECH R&D LIMITED  
208 BATH ROAD  
SLOUGH, SL1 3WE  
BERKSHIRE  
GB  
8121485001  
ENGLAND AND WALES

4. Title of the invention

ANTIBODIES

5. Name of your agent (if you have one)

DR. JOHN THOMPSON, CPA, EPA

"Address for service" in the United Kingdom to which all correspondence should be sent (including the postcode)

CELLTECH R&D LIMITED  
208 BATH ROAD  
SLOUGH, SL1 3WE  
BERKSHIRE

Patents ADP number (if you know it)

8121485001

6. If you are declaring priority from one or more earlier patent applications, give the country and the date of filing of the or of each of these earlier applications and (if you know it) the or each application number

Country

Priority application number  
(if you know it)

Date of filing  
(day / month / year)

7. If this application is divided or otherwise derived from an earlier UK application, give the number and the filing date of the earlier application

Number of earlier application

Date of filing  
(day / month / year)

8. Is a statement of inventorship and of right to grant of a patent required in support of this request? (Answer 'Yes' if

YES

- a) any applicant named in part 3 is not an inventor, or
- b) there is an inventor who is not named as an applicant, or
- c) any named applicant is a corporate body.  
See note (d))

Patents Form 1/77

9. Enter the number of sheets for any of the following items you are filing with this form.  
Do not count copies of the same document

Any other documents  
(please specify)

11.

I/We request the grant of a patent on the basis of this application.

Signature

Date 04.02.04

12. Name and daytime telephone number of person to contact in the United Kingdom

DR. TRICIA DIGGLE - 01753 534655

**Warning**

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

**Notes**

- a) If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- b) Write your answers in capital letters using black ink or you may type them.
- c) If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- d) If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- e) Once you have filled in the form you must remember to sign and date it.
- f) For details of the fee and ways to pay please contact the Patent Office.

## ANTIBODIES

The present invention relates to improved methods for the selection of cells producing antibodies specific for an antigen of interest.

- 5       Antibodies are a particular class of proteins which have been developed for therapeutic and diagnostic purposes. The isolation of cells producing antibody specific for an antigen of interest is historically performed using hybridoma technology. Other methods include isolating antibodies from bacterially expressed libraries which are limited in that they are restricted by practical limits to the size of libraries and the requirement for the
- 10      antibody to be properly folded and expressed in bacteria. A number of alternative methods have been designed to enable high affinity antibodies generated during *in vivo* immune responses to be isolated from any species (Babcock *et al.*, 1996, Proc. Natl. Acad. Sci, 93, 7843-7848; WO 92/02551; de Wildt *et al.*, 1997, J. Immunol. Methods, 207:61-67 and in Lagerkvist, *et al.*, 1995, BioTechniques 18(5):862-869).
- 15      Methods for the detection and isolation of cells producing antibody specific for an antigen of interest are well-known in the art and include isolation of antibody producing cells by binding to biotinylated antigen and capture on streptavidin-beads, panning against antigen-coated plastic surfaces, rosetting with antigen-coated red blood cells, flow cytometric analysis and single cell sorting where the antigen is fluorescently labelled. The
- 20      major drawback of these methods is that the presentation of antigen is generally random such that masking of the antigenic epitope which is specifically recognised by the antibody producing cell can occur. In particular, where the antigen of interest is a protein, the labelling of the antigen for example with a fluorescent label, is a chemical modification of the surface of the antigen which can decrease the affinity of an antibody-antigen interaction
- 25      or prevent interaction. Where the antigens of interest are small proteins or short peptides the introduction of a chemical modification in the form of a label, such as a fluorescent label, may interfere such that little or no binding of antigen to specific antibody occurs.

- Similar problems exist where the antigen of interest is provided tagged as a fusion protein. The incorporation of an additional sequence on the C-terminus or N-terminus of a
- 30      protein can result in aberrant folding such that the antigen is not folded into a native conformation. As such, antigenic epitopes exposed within, for example, a host immunised with native antigen may not be accessible on a fusion protein of the same antigen. Thus, at the step of enrichment of cells producing antibody specific for the native antigen, those cells

producing antibody to epitopes which are masked or altered in the fusion protein will not be detected and isolated.

Using unlabelled or untagged antigen is therefore particularly advantageous in that this avoids any modification of the antigen which can modify or mask interaction sites and 5 which, in turn, can result in absence of detection of an antibody specific for the antigen of interest. Accordingly, provided is a method of enriching a population of cells in those cells which produce an antibody that recognises an antigen of interest, comprising:

- a) bringing said population into contact with an antibody that recognises a marker which is essentially unique to those cells present in the population which are capable 10 of producing an antibody, said antibody being attached to a first fluorescent label;
- b) bringing said population into contact with the antigen of interest; and
- c) bringing said population into contact with a sample comprising an antibody that recognises said antigen, said antibody being attached to a second fluorescent label; and
- 15 d) separating from the population those cells which are detectable by virtue of being associated with the first and second fluorescent labels.

The terms 'cells which are capable of producing an antibody' or 'antibody producing cell' include any cell secreting an antibody, such as a B-lymphocyte, a plasma cell, a 20 plasmablast, an activated B cell or a memory B cell. Such cells may produce antibody of any affinity, for example high affinity antibody or lower affinity antibody. The methods of the invention are not dependent on the affinity of the antibody produced by such cells. A population comprising antibody producing cells for use in the invention may be obtained from an animal which has either been immunized with an antigen of interest, or which has 25 developed an immune response to an antigen as a result of disease. For example but without limitation, the population can comprise a peripheral blood cell sample, spleen cells or cells derived from a lymph node. Other populations comprising antibody producing cells for use in the present invention may include a population of hybridoma cells, a population comprising any transformed cell, and in particular, a population comprising any mammalian 30 cells which express immunoglobulin genes or parts thereof. Examples of such mammalian cells include but are not limited to NS0, CHO, COS and 293 cells. In a preferred embodiment, the populations of antibody producing cells for use in the present invention produce a range of antibodies with different binding specificities. As such, the methods of the invention are not dependent on the affinity of the antibody produced by said cells. In

another embodiment, the population of cells comprising at least one cell producing an antibody that recognises an antigen of interest is derived from several sources, for example but without limitation from several lymph nodes which may be from one or more animals. It will also be apparent that samples or populations of cells derived from two or more animals

5 can be pooled for use in the methods of the invention. In a particular embodiment, the population of cells is derived from a human who has been exposed to an antigen of interest or who has developed an immune response to an antigen as a result of a disease or condition. In such a case, the sample comprising the population of cells for enrichment is preferably a peripheral blood sample or one or more lymph nodes.

10 Preferably, the population is suspended in an appropriate medium for use in the methods of the invention. An appropriate medium for the assay will be one that provides at least the minimum requirements for short-term maintenance of cellular integrity and cellular structures, such as an isotonic buffer. One example, but without limitation, is immune cell medium comprising Roswell Park Memorial Institute medium (RPMI) + 10% foetal bovine  
15 serum; 50µM 2-β-mercaptoethanol; 2mM glutamine; 20mM Hepes; and 1x Penicillin and Streptomycin. Under such conditions the antibody producing cells produce and secrete antibodies.

20 A population comprising antibody producing cells may be depleted of unwanted cells such as for example but without limitation, red blood cells, T cells, macrophages or other cells if so desired. In the methods of the invention the population of cells provided, at least one of which is capable of producing an antibody, is preferably depleted of any red blood cells for example using centrifugation or red cell lysis as known in the art.

25 The term 'antibody' as used herein includes any recombinant or naturally occurring immunoglobulin molecule such as a member of the IgG class e.g. IgG1, including a monoclonal or polyclonal antibody, any antigen binding immunoglobulin fragment, such as Fv, Fab' and F(ab')<sub>2</sub> fragments, and any derivatives thereof, such as single chain Fv fragments. The term antibody that 'recognises an antigen' includes an antibody that binds to, or is specific for, an antigen of interest. Most preferably, an antibody binds to the antigen of interest and does not bind to or recognise other unrelated antigens.

30 In the methods of the invention, the antibody of part a) above recognises a marker which is essentially unique to those cells capable of producing an antibody, for example a marker essentially unique to B cells. 'Essentially unique' includes a marker that is predominantly present on those cells capable of producing antibody compared to other cells

types, but not necessarily to the exclusion of all other cell types. Hence, such a marker may also be present on one or two or even three or more other cell types. Examples of preferred markers include without limitation, CD5, CD9, CD10, CD19, CD20, CD21, CD22, CD45, CD45 RC, although one skilled in the art will recognise that many of the 'CD' markers 5 present on B cells can be used. In one example, the antibody of part a) above is a monoclonal antibody. Cells expressing a marker recognised by an antibody of part a) above will be distinguished by virtue of having the first label attached. Those cells that are not capable of producing antibody will be distinguished by being unlabelled or negative. In a further embodiment, those cells, within a population, which are capable of producing an 10 antibody may be attached to two labels. In such a case, an antibody that recognises a second, different marker essentially unique to said cells is labelled with a third label, *i.e.* a label that is different from those which are attached to the antibodies of parts a) and b), above. Those antibody producing cells within the population provided will thus be distinguished by having two labels attached. Thus, the selection of those cells which carry the chosen markers is 15 made possible by distinguishing from those which carry only one marker, or no marker in which case said cells will be unlabelled or negative.

In the methods of the invention, the antibody of part b) above is most preferably a polyclonal antibody that is from the same source as that of the population of cells for enrichment. In a preferred example, the source of the population of cells is an animal 20 immunised with an untagged antigen of interest and the polyclonal antibody is prepared from a sample of blood from said immunised animal. In another embodiment, the antibody of part b) above is present in a pool of polyclonal sera; for example it is present in a pool of sera from at least two animals which have been immunised with the antigen of interest. It will be apparent to one skilled in the art that the polyclonal antibody may be present as a serum 25 sample, but is more preferably prepared as an IgG fraction. Methods for producing an IgG fraction are well known in the art and include affinity chromatography such as Protein A or Protein G affinity chromatography, and ammonium sulphate or caprylic acid precipitation. The polyclonal antibody may be a whole IgG or a fragment thereof such as a Fab', F(ab')<sub>2</sub> or 30 Fab fragment. Fragments may be produced using any method known in the art, for example using papain or pepsin digestion. In an alternative embodiment, the antibody of part b) above is a monoclonal antibody.

Labels of use in the methods of the invention are fluorescent labels. Appropriate fluorescent labels are well known in the art, as are methods for performing the labelling of antibodies with such labels. Such labels can include, but are not limited to, Alexa Fluor 488,

R-phycoerythrin, Aqua, Texas-Red, FITC, rhodamine, a rhodamine derivative, fluorescein, a fluorescein derivative, cascade blue, Cy5 or Cy3. Preferably, the first or second fluorescent label is Alexa Fluor 488 or R-phycoerythrin. It is understood that the first and second labels, and any subsequent labels, if used, are different labels. In a preferred embodiment, the

- 5 methods of the invention utilise two labels, *i.e.* a first and second fluorescent label. Labelled antibodies are preferably used at, for example but without limitation, 1-5 $\mu$ g/ml and incubation of such antibodies with a cell sample is preferably performed in the cold for an appropriate length of time, for example 60mins. It will be apparent to one skilled in the art that the concentration of antibody may be less or more than the stated values, above, and  
10 hence may range from, for example 0.1 $\mu$ g/ml or less to 10 $\mu$ g/ml or more.

In the methods of the invention the antigen is provided in an untagged form. The term 'antigen' includes any substance that can be recognised by an antibody, including proteins, glycoproteins and carbohydrates. Preferably these antigens include biologically active proteins, such as hormones, cytokines, and their cell surface receptors, bacterial or  
15 parasitic cell membranes or purified components thereof, and viral antigens. Most preferably, the antigen is available in a pure form obtained either by direct purification from the native source or by recombinant expression and purification of said antigen. A pure form includes antigens that are at least 75%, 80%, 85% or 90% free from contaminants, and preferably at least 95% or 99% free from contaminants. Most preferably, antigens are 100%  
20 pure or have no detectable contaminants. In one embodiment, the antigen is expressed recombinantly as a fusion protein and the fusion tag has been removed prior to use of the antigen. Removal of such tags is well known in the art and such removal may leave a small number of residual amino acid residues which are not normally present at the N-terminus or C-terminus of the antigen in its native state, *e.g.* residues from a linker region and/or the  
25 region of cleavage of the tag. Thus, the term 'untagged' antigen includes antigens which have had a tag removed regardless of whether or not additional amino acid residues remain attached to the antigen as a result of the cleavage. Examples of such tags are known in the art and expression vectors incorporating nucleic acid code for such tags are commercially available for example, but not limited to, myc, FLAG or His tags.

- 30 In a particular embodiment, the antigen is presented on the surface of a cell. Such an antigen may be endogenous or recombinant.

Preferably, incubation of the antigen at a concentration of approximately 1 $\mu$ M to 1pM in the presence of a population of, for example but without limitation, approximately 10<sup>7</sup> or 10<sup>8</sup> white blood cells some of which are capable of producing antibody is performed

on ice for approximately 60min. It is understood that the number of cells may be less or more than  $10^7$ , and may be  $10^6$ ,  $10^5$ ,  $10^4$  or less, or  $10^9$  or more as desired. The concentration of antigen may also be varied and may be chosen as appropriate and understood by one skilled in the art. In one embodiment, low concentrations of antigen can be used to bias 5 towards selecting B cells that produce high affinity antibody.

In a preferred embodiment, parts a), b), and c) are performed simultaneously, the first and second labels are fluorescent labels and the performance is optionally followed by at least one wash step. In another embodiment parts a) and b), or a) and c), or b) and c), are performed simultaneously and optionally comprise at least one wash step. Wash steps may 10 be performed by any means known in the art, for example using phosphate buffered saline (PBS) or other appropriate media. The population of cells may be separated from any incubation or wash media using, for example but without limitation, centrifugation. Alternatively, cells may be left to settle under gravity followed by removal of the washing buffer or other media.

15 In another embodiment, parts a), b) and c) are performed consecutively, in any order, such that the performance of part a) may be followed by the performance of part b), and then part c). It will be apparent to a person skilled in the art that any permutation is possible, e.g. part a), then part c) followed by part b), or part b) then part a) followed by part c), etc. It will also be apparent that one or more washing steps as described above may be carried out after 20 the performance of any of parts a) to d) or combination thereof.

In the methods of the invention, separation of those cells that are attached to both a first and a second label from a population of cells is most preferably performed using fluorescence activated cell sorting (FACS). Alternatively, said cells are identified using a fluorescence microscope. Cells identified using the latter method may be isolated by 25 micromanipulation. Thus, an enriched population of cells producing an antibody that recognises an antigen of interest can be prepared using the methods of the invention. In one preferred embodiment, the enriched population of cells is subject to at least one washing step. Alternatively, the enriched population of cells is not washed.

An enriched population of cells obtained using any of the methods of the invention 30 may be further separated, if desired, to obtain and clone one or more single antibody producing cells using any method known in the art. Methods to obtain and clone single antibody producing cells include methods such as, but not limited to, the selected lymphocyte antibody method (SLAM) described in WO 92/02551 and Babcock *et al.*, 1996, Proc. Natl. Acad. Sci USA 93:7843-7848. Other techniques include those described by de

Wildt et al., 1997, J. Immunol. Methods, 207:61-67 and Lagerkvist et al., 1995, BioTechniques 18(5):862-869. The above methods rely on the isolation of individual antibody producing cells which are then clonally expanded, followed by screening for those clones which are producing an antibody that recognises an antigen of interest, and, if desired,  
5 the subsequent identification of the sequence of their variable heavy ( $V_H$ ) and light ( $V_L$ ) chain genes.

Alternatively, the enriched population of cells producing antibody that recognises an antigen of interest may be plated into one or more wells and screened for antibody production followed sequence identification, if desired, as above. In such a case, the  
10 enriched population of cells is divided such that a plurality of cells is placed in the well for culture. It is preferred that the wells are seeded with between 2 and 100 B cells; more preferably with between 2 and 75 B cells; more preferably between 5 and 50 B cells; more preferably between 5 and 25 B cells; more preferably between 5 and 15 B cells; more preferably between 8 and 12 B cells; yet more preferably about 10 B cells / well.

15 In one embodiment, the B cells are cultured for about, or at least, 4, 5, 6, 7, 8, 9 or 10 days or up to one month. Preferably, the B cells are cultured for about 5 to 10 days, more preferably for about 6 to 9, or 6 to 8 days.

Most preferably, the cells are cultured under conditions suitable for the clonal expansion of the B cells. Clonal expansion results in a greater quantity of antibody being  
20 produced and higher levels of mRNA expression. Clonal expansion is preferably performed in the presence of an antigen to which the antibody with the desired function binds which may assist in the isolation of higher affinity antibodies via in vitro affinity maturation.

Conditions suitable for the clonal expansion of B cells are well known in the art. Important conditions include the culture medium, the time for which the cells are cultured,  
25 temperature and atmospheric CO<sub>2</sub>.

Preferably, the B cells are cultured with irradiated EL-4 cells in T cell conditioned media. More preferably, the B cells are cultured with irradiated mutant murine EL-4 thymoma cells, EL-4/B5, in conjunction with human T-cell/macrophage supernatant as a source of proliferation and differentiation factors. The EL-4/B5 cells activate the B-cells via  
30 a MHC-nonrestricted direct cell-cell interaction. The activation signal itself is not mitogenic but sensitizes the B cells to respond to one (IL-2) or several cytokines present in human T-cell supernatant.

Once the cells have been cultured, a plurality of the cultured cells may be screened to ascertain the presence of cells capable of producing an antibody having the desired function. Preferably, this involves screening the culture supernatant of said plurality of cultured cells. Where cells have been cultured in a series of wells, the wells can be individually assayed

5 (e.g. by taking culture supernatant from the wells) for the presence of cells capable of producing an antibody recognising the antigen of interest to thereby identify one or more wells which are positive for the presence of cells capable of producing an antibody having the desired function. Said antibodies can then be obtained from a positive well. The antibodies can be synthesized directly or indirectly from the cells present in the well.

10 Accordingly, provided is a method of enriching a population of cells in those cells which produce an antibody that recognises an antigen of interest, comprising:

- a) bringing said population into contact with an antibody that recognises a marker which is essentially unique to those cells present in the population which are capable of producing an antibody, said antibody being attached to a first fluorescent label;
- 15 b) bringing said population into contact with the antigen of interest;
- c) bringing said population into contact with a sample comprising an antibody that recognises said antigen, said antibody being attached to a second fluorescent label;
- d) separating from the population those cells which are detectable by virtue of being associated with the first and second fluorescent labels;
- 20 e) culturing a plurality of those cells associated with the antigen-antibody-particle complex;
- f) screening the cultured cells to identify those cells capable of producing an antibody which recognises an antigen of interest; and
- g) isolating said antibody directly or indirectly from the cells.

25 Screening for cells producing antibodies recognising the antigen of interest may be performed by any means known in the art, such as by enzyme-linked immunosorbent assay (ELISA) or by screening for a functional activity such as neutralisation of antigen activity, or antagonistic or agonistic activities. Such assays are known in the art, for example, functional  
30 screening of receptor/ligand binding. Antibodies may be selected based on binding affinities such as, for example, may be determined using a BIACore machine, or using a competitive radioimmunoassay.

The desired antibody, *i.e.* the antibody recognising the antigen of interest, may be isolated directly or indirectly from the cultured cells or from descendants thereof. Direct

isolation can be achieved by purification of secreted antibody from the clonal culture supernatant using standard, well known techniques. Alternatively, indirect isolation is performed. Such antibodies are synthesised by isolating the  $V_L$  and  $V_H$  chain gene regions or the entire genes may be cloned and used to produce recombinant antibodies that recognise  
5 the antigen of interest.

Such antibodies can include functionally active fragments, derivatives or analogues and may be, but are not limited to, bi-, tri- or tetra-valent antibodies, humanized or chimeric antibodies, single chain antibodies, Fab fragments, Fab' and  $F(ab')_2$  fragments, fragments produced by a Fab expression library, anti-idiotypic (anti-Id) antibodies, epitope-binding  
10 fragments and derivatives of any of the above, e.g. single chain FV fragments. Humanized antibodies are antibody molecules from non-human species having one or more complementarity determining regions (CDRs) from the non-human species and a framework region from a human immunoglobulin molecule (see, e.g. US 5,585,089). The methods for creating these antibody molecules are well known in the art (see for example, Boss et al., US  
15 4,816,397; Cabilly et al., US 6,331,415; Shrader et al., WO 92/02551; Ward et al., 1989, Nature, 341, 544; Orlandi et al., 1989, Proc.Natl.Acad.Sci. USA, 86, 3833; ; Riechmann et al., 1988, Nature, 322, 323; Bird et al, 1988, Science, 242, 423; Queen et al., US 5,585,089; Adair, WO91/09967; Mountain and Adair, 1992, Biotechnol. Genet. Eng. Rev, 10, 1-142).

Chimeric antibodies are those antibodies encoded by immunoglobulin genes that  
20 have been genetically engineered so that the light and heavy chain genes are composed of immunoglobulin gene segments belonging to different species. These chimeric antibodies are likely to be less antigenic. Bivalent antibodies may be made by methods known in the art (Milstein et al., 1983, Nature 305:537-539; WO 93/08829, Traunecker et al., 1991, EMBO J. 10:3655-3659). Bi-, tri- and tetra-valent antibodies may comprise multiple  
25 specificities or may be monospecific (see for example WO 92/22853).

The types of expression systems available to produce these antibody molecules include bacterial, yeast, insect and mammalian expression systems, the methods for which are well known in the art (Verma et al., 1998, Journal of Immunological Methods, 216, 165-181). Techniques for the production of single chain antibodies, such as those described in  
30 US 4,946,778 can also be adapted to produce single chain antibodies to the antigen of interest. Also, transgenic mice or other organisms, including other mammals, may be used to express humanized antibodies.

Antibodies obtained using the above methods may be used without further modification, or if desired following modification including conjugation to one or more

reporter or effector molecules, for any suitable diagnostic or therapeutic purpose. An antibody, optionally conjugated to a therapeutic moiety, can be used therapeutically alone or in combination with a cytotoxic factor(s) and/or cytokine(s). In particular, antibodies can be conjugated to a therapeutic agent, such as a cytotoxic agent, a radionuclide or drug moiety to 5 modify a given biological response. The therapeutic agent is not to be construed as limited to classical chemical therapeutic agents. For example, the therapeutic agent may be a drug moiety which may be a protein or polypeptide possessing a desired biological activity. Such moieties may include, for example and without limitation, a toxin such as abrin, ricin A, pseudomonas exotoxin, or diphtheria toxin, a protein such as tumour necrosis factor,  $\alpha$ - 10 interferon,  $\beta$ -interferon, nerve growth factor, platelet derived growth factor or tissue plasminogen activator, a thrombotic agent or an anti-angiogenic agent, e.g. angiostatin or endostatin, or, a biological response modifier such as a lymphokine, interleukin-1 (IL-1), interleukin-2 (IL-2), interleukin-6 (IL-6), granulocyte macrophage colony stimulating factor (GM-CSF), granulocyte colony stimulating factor (G-CSF), nerve growth factor (NGF) or 15 other growth factor.

Therapeutic agents also include cytotoxins or cytotoxic agents including any agent that is detrimental to (e.g. kills) cells. Examples include taxol, cytochalasin B, gramicidin D, ethidium bromide, emetine, mitomycin, etoposide, tenoposide, vincristine, vinblastine, colchicine, doxorubicin, daunorubicin, dihydroxy anthracin dione, mitoxantrone, 20 mithramycin, actinomycin D, 1-dehydrotestosterone, glucocorticoids, procaine, tetracaine, lidocaine, propranolol, and puromycin and analogs or homologs thereof. Therapeutic agents also include, but are not limited to, antimetabolites (e.g. methotrexate, 6-mercaptopurine, 6-thioguanine, cytarabine, 5-fluorouracil decarbazine), alkylating agents (e.g. mechlorethamine, thioepa chlorambucil, melphalan, carmustine (BSNU) and lomustine 25 (CCNU), cyclothosphamide, busulfan, dibromomannitol, streptozotocin, mitomycin C, and cis-dichlorodiamine platinum (II) (DDP) cisplatin), anthracyclines (e.g. daunorubicin (formerly daunomycin) and doxorubicin), antibiotics (e.g. dactinomycin (formerly actinomycin), bleomycin, mithramycin, anthramycin (AMC), calicheamicins or duocarmycins), and anti-mitotic agents (e.g. vincristine and vinblastine).

30 Other therapeutic moieties may include radionuclides such as  $^{111}\text{In}$  and  $^{90}\text{Y}$ ,  $\text{Lu}^{177}$ , Bismuth<sup>213</sup>, Californium<sup>252</sup>, Iridium<sup>192</sup> and Tunsten<sup>188</sup>/Rhenium<sup>188</sup>; or drugs such as but not limited to, alkylyphosphocholines, topoisomerase I inhibitors, taxoids and suramin.

Techniques for conjugating such therapeutic agents to antibodies are well known in the art (see, e.g. Armon *et al.*, "Monoclonal Antibodies For Immunotargeting Of Drugs In Cancer Therapy", in *Monoclonal Antibodies And Cancer Therapy*, Reisfeld *et al.*, eds., 1985 pp. 243-56, ed. Alan R. Liss, Inc; Hellstrom *et al.*, "Antibodies For Drug Delivery", in Controlled Drug Delivery, 2nd Ed., Robinson *et al.*, eds., 1987, pp. 623-53, Marcel Dekker, Inc.; Thorpe, "Antibody Carriers Of Cytotoxic Agents In Cancer Therapy: A Review", in *Monoclonal Antibodies '84: Biological And Clinical Applications*; Pinchera *et al.*, 1985, eds., pp. 475-506; "Analysis, Results, And Future Prospective Of The Therapeutic Use Of Radiolabelled Antibody In Cancer Therapy", in *Monoclonal Antibodies For Cancer Detection And Therapy*, Baldwin *et al.* (eds.), 1985, pp. 303-16, Academic Press; Thorpe *et al.*, 1982 "The Preparation And Cytotoxic Properties Of Antibody-Toxin Conjugates", *Immunol. Rev.*, 62:119-58 and Dubowchik *et al.*, 1999, *Pharmacology and Therapeutics*, 83, 67-123).

The antibodies for use in the invention include analogues and derivatives that are modified, for example but without limitation, by the covalent attachment of any type of molecule. Preferably, said attachment does not impair immunospecific binding. In one aspect, an antibody can be conjugated to a second antibody to form an antibody heteroconjugate (see US 4,676,980).

In other embodiments, the invention provides the therapeutic use of fusion proteins of the antibodies (or functionally active fragments thereof), for example but without limitation, where the antibody or fragment thereof is fused via a covalent bond (e.g. a peptide bond), at optionally the N-terminus or the C-terminus, to an amino acid sequence of another protein (or portion thereof; preferably at least a 10, 20 or 50 amino acid portion of the protein). Preferably the antibody, or fragment thereof, is linked to the other protein at the N-terminus of the constant domain of the antibody. In another aspect, an antibody fusion protein may facilitate depletion or purification of a polypeptide as described herein, increase half-life *in vivo*, and enhance the delivery of an antigen across an epithelial barrier to the immune system.

Where the fusion protein is an antibody fragment linked to an effector or reporter molecule, this may be prepared by standard chemical or recombinant DNA procedures. For instance, it may have a macrocycle for chelating a heavy metal atom, or a toxin, such as ricin, attached to it by a covalent bridging structure. A preferred effector group is a polymer molecule, which may be attached to the modified Fab fragment to increase its half-life *in vivo*.

The polymer molecule may, in general, be a synthetic or a naturally occurring polymer, for example an optionally substituted straight or branched chain polyalkylene, polyalkenylene or polyoxyalkylene polymer or a branched or unbranched polysaccharide, e.g. a homo- or hetero- polysaccharide.

- 5 Particular optional substituents which may be present on the above-mentioned synthetic polymers include one or more hydroxy, methyl or methoxy groups. Particular examples of synthetic polymers include optionally substituted straight or branched chain poly(ethyleneglycol), poly(propyleneglycol) poly(vinylalcohol) or derivatives thereof, especially optionally substituted poly(ethyleneglycol) such as methoxypoly(ethyleneglycol)  
10 or derivatives thereof.

Particular naturally occurring polymers include lactose, amylose, dextran, glycogen or derivatives thereof.

- 15 "Derivatives" as used herein is intended to include reactive derivatives, for example thiol-selective reactive groups such as maleimides and the like. The reactive group may be linked directly or through a linker segment to the polymer. It will be appreciated that the residue of such a group will in some instances form part of the product as the linking group between the antibody fragment and the polymer.

- 20 The size of the polymer may be varied as desired, but will generally be in an average molecular weight range from 500Da to 50000Da, preferably from 5000 to 40000Da and  
25 more preferably from 25000 to 40000Da. The polymer size may in particular be selected on the basis of the intended use of the product. Thus, for example, where the product is intended to leave the circulation and penetrate tissue, for example for use in the treatment of a tumour, it may be advantageous to use a small molecular weight polymer, for example with a molecular weight of around 5000Da. For applications where the product remains in the circulation, it may be advantageous to use a higher molecular weight polymer, for example having a molecular weight in the range from 25000Da to 40000Da.

Particularly preferred polymers include a polyalkylene polymer, such as a poly(ethyleneglycol) or, especially, a methoxypoly(ethyleneglycol) or a derivative thereof, and especially with a molecular weight in the range from about 25000Da to about 40000Da.

- 30 Each polymer molecule attached to the modified antibody fragment may be covalently linked to the sulphur atom of a cysteine residue located in the fragment. The covalent linkage will generally be a disulphide bond or, in particular, a sulphur-carbon bond.

Where desired, the antibody fragment may have one or more effector or reporter molecules attached to it. The effector or reporter molecules may be attached to the antibody

fragment through any available amino acid side-chain or terminal amino acid functional group located in the fragment, for example any free amino, imino, hydroxyl or carboxyl group.

An activated polymer may be used as the starting material in the preparation  
5 of polymer-modified antibody fragments as described above. The activated polymer may be any polymer containing a thiol reactive group such as an  $\alpha$ -halocarboxylic acid or ester, e.g. iodoacetamide, an imide, e.g. maleimide, a vinyl sulphone or a disulphide. Such starting materials may be obtained commercially (for example from Nektar, formerly Shearwater Polymers Inc., Huntsville, AL, USA) or may be prepared from commercially available  
10 starting materials using conventional chemical procedures. Particular PEG molecules include 20K methoxy-PEG-amine (obtainable from Nektar, formerly Shearwater; Rapp Polymere; and SunBio) and M-PEG-SPA (obtainable from Nektar, formerly Shearwater).

Standard chemical or recombinant DNA procedures in which the antibody fragment is linked either directly or via a coupling agent to the effector or reporter molecule either before  
15 or after reaction with the activated polymer as appropriate may be used. Particular chemical procedures include, for example, those described in WO 93/06231, WO 92/22583, WO 90/09195, WO 89/01476, WO 99/15549 and WO03/031581. Alternatively, where the effector or reporter molecule is a protein or polypeptide the linkage may be achieved using recombinant DNA procedures, for example as described in WO 86/01533 and EP 0392745.

20 Most preferably antibodies are attached to poly(ethyleneglycol) (PEG) moieties. Preferably, a modified Fab fragment is PEGylated, *i.e.* has PEG (poly(ethyleneglycol)) covalently attached thereto, *e.g.* according to the method disclosed in EP 0948544 [see also "Poly(ethyleneglycol) Chemistry, Biotechnical and Biomedical Applications", 1992, J. Milton Harris (ed), Plenum Press, New York, "Poly(ethyleneglycol) Chemistry and  
25 Biological Applications", 1997, J. Milton Harris and S. Zalipsky (eds), American Chemical Society, Washington DC and "Bioconjugation Protein Coupling Techniques for the Biomedical Sciences", 1998, M. Aslam and A. Dent, Grove Publishers, New York; Chapman, A. 2002, Advanced Drug Delivery Reviews 2002, 54:531-545]. In one embodiment, a PEG modified Fab fragment has a maleimide group covalently linked to a  
30 single thiol group in a modified hinge region. A lysine residue may be covalently linked to the maleimide group. To each of the amine groups on the lysine residue may be attached a methoxypoly(ethyleneglycol) polymer having a molecular weight of approximately 20,000

Da. The total molecular weight of the entire effector molecule may therefore be approximately 40,000 Da.

Antibodies prepared directly or indirectly as a result of using the methods of the invention find use in the treatment and/or prophylaxis of a disease or condition depending on 5 the antigen of interest selected. For example but without limitation, an antigen restricted to expression on the surface of tumour cells may be selected for immunisation of one or more animals.

Therefore, according to the invention provided is the use of an antibody prepared using the methods of the invention for the manufacture of a medicament for the treatment 10 and/or prophylaxis of a condition or disease, for example, cancers, autoimmune disorders or inflammatory disorders. Also provided is an antibody for use in therapy, for example therapy of a disease or condition such as cancers, autoimmune disorders or inflammatory disorders. For such use the antibodies will generally be administered in the form of a pharmaceutical composition.

15 Thus, according to the invention there is provided a pharmaceutical composition comprising an antibody that recognises an antigen of interest and a pharmaceutically acceptable diluent, excipient and /or carrier.

When a reference is made herein to a method of treating or preventing a disease or condition using a particular antibody or combination of antibodies, it is to be understood that 20 such a reference is intended to include the use of that antibody or combination of antibodies in the preparation of a medicament for the treatment and/or prophylaxis of the disease or condition.

The composition will usually be supplied as part of a sterile, pharmaceutical 25 composition that will normally include a pharmaceutically acceptable carrier. This composition may be in any suitable form (depending upon the desired method of administering it to a patient).

Antibodies of the invention may be administered to a subject by any of the routes conventionally used for drug administration, for example they may be administered 30 parenterally, orally or by inhalation. The most suitable route for administration in any given case will depend on the particular antibody, the disease or condition involved, the subject, and the nature and severity of the disease or condition and the physical condition of the subject.

The antibodies may be administered in combination, e.g. simultaneously, sequentially or separately, with one or more other therapeutically active compounds, e.g. anti-tumour or anti-inflammatory compounds.

Pharmaceutical compositions may be conveniently presented in unit dose forms

- 5 containing a predetermined amount of an antibody of the invention per dose. Such a unit may contain for example but without limitation, 750mg/kg to 0.1mg/kg depending on the condition being treated, the route of administration and the age, weight and condition of the subject.

Pharmaceutically acceptable carriers for use in the invention may take a wide variety of forms depending, e.g. on the route of administration.

- 10 Compositions for oral administration may be liquid or solid. Oral liquid preparations may be in the form of, for example, aqueous or oily suspensions, solutions, emulsions, syrups or elixirs, or may be presented as a dry product for reconstitution with water or other suitable vehicle before use. Oral liquid preparations may contain suspending agents as known in the art.

- 15 In the case of oral solid preparations such as powders, capsules and tablets, carriers such as starches, sugars, microcrystalline cellulose, diluents, granulating agents, lubricants, binders, disintegrating agents, and the like may be included. Because of their ease of administration, tablets and capsules represent the most advantageous oral dosage unit form in which case solid pharmaceutical carriers are generally employed. In addition to the  
20 common dosage forms set out above, antibodies of the invention may also be administered by controlled release means and/or delivery devices. Tablets and capsules may comprise conventional carriers or excipients such as binding agents for example, syrup, acacia, gelatin, sorbitol, tragacanth, or polyvinylpyrrolidone; fillers, for example lactose, sugar, maize-starch, calcium phosphate, sorbitol or glycine; tableting lubricants, for example magnesium  
25 stearate, talc, polyethylene glycol or silica; disintegrants, for example potato starch; or acceptable wetting agents such as sodium lauryl sulphate. The tablets may be coated by standard aqueous or non-aqueous techniques according to methods well known in normal pharmaceutical practice.

- Pharmaceutical compositions of the present invention suitable for oral administration  
30 may be presented as discrete units such as capsules, cachets or tablets, each containing a predetermined amount of the antibody, as a powder or granules, or as a solution or a suspension in an aqueous liquid, a non-aqueous liquid, an oil-in-water emulsion or a water-in-oil liquid emulsion. Such compositions may be prepared by any of the methods of pharmacy but all methods include the step of bringing into association the antibody with the

carrier, which constitutes one or more necessary ingredients. In general, the compositions are prepared by uniformly and intimately admixing the antibody with liquid carriers or finely divided solid carriers or both, and then, if necessary, shaping the product into the desired presentation. For example, a tablet may be prepared by compression or moulding, optionally 5 with one or more accessory ingredients.

Pharmaceutical compositions suitable for parenteral administration may be prepared as solutions or suspensions of the antibodies of the invention in water suitably mixed with a surfactant such as hydroxypropylcellulose. Dispersions can also be prepared in glycerol, liquid polyethylene glycols, and mixtures thereof in oils. Under ordinary conditions of 10 storage and use, these preparations contain a preservative to prevent the growth of microorganisms.

The pharmaceutical forms suitable for injectable use include aqueous or non-aqueous sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats and solutes which render the composition isotonic with the blood of the intended recipient, and aqueous 15 and non-aqueous sterile suspensions which may include suspending agents and thickening agents. Extemporaneous injection solutions, dispersions and suspensions may be prepared from sterile powders, granules and tablets.

Pharmaceutical compositions can be administered with medical devices known in the art. For example, in a preferred embodiment, a pharmaceutical composition of the 20 invention can be administered with a needleless hypodermic injection device, such as the devices disclosed in US 5,399,163; 5,383,851; 5,312,335; 5,064,413; 4,941,880; 4,790,824; or 4,596,556. Examples of well-known implants and modules useful in the present invention 25 include: US 4,487,603, which discloses an implantable micro-infusion pump for dispensing medication at a controlled rate; US 4,486,194, which discloses a therapeutic device for administering medicaments through the skin; US 4,447,233, which discloses a medication infusion pump for delivering medication at a precise infusion rate; US 4,447,224, which discloses a variable flow implantable infusion apparatus for continuous drug delivery; US 4,439,196, which discloses an osmotic drug delivery system having multi-chamber compartments; and US 4,475,196, which discloses an osmotic drug delivery system. Many 30 other such implants, delivery systems, and modules are known to those skilled in the art.

In certain embodiments, the pharmaceutical compositions of the invention can be formulated to ensure proper distribution *in vivo*. For example, the blood-brain barrier excludes many highly hydrophilic compounds and it may be preferable to deliver pharmaceutical compositions in liposomes. Thus, in one embodiment of the invention, the

antibodies of the invention are formulated in liposomes; in a more preferred embodiment, the liposomes include a targeting moiety. In a most preferred embodiment, the therapeutic compounds in the liposomes are delivered by bolus injection to a site proximal to the problem area, *e.g.* proximal to a tumour. For methods of manufacturing liposomes, see, *e.g.*

- 5 US 4,522,811; 5,374,548; and 5,399,331. The liposomes may comprise one or more moieties which are selectively transported into specific cells or organs, thus enhancing targeted drug delivery (*see, e.g.* Ranade, VV. 1989, *J. Clin. Pharmacol.* 29:685). Exemplary targeting moieties include folate or biotin (*see, e.g.* U.S. Patent 5,416,016.); mannosides (Umezawa *et al.*, 1988, *Biochem. Biophys. Res. Commun.* 153:1038); antibodies (Bloeman,  
10 PG. *et al.*, 1995, *FEBS Lett.* 357:140; M. Owais *et al.*, 1995, *Antimicrob. Agents Chemother.* 39:180); surfactant protein A receptor (Briscoe *et al.*, 1995, *Am. J. Physiol.* 1233:134), different species of which may comprise the formulations of the inventions, as well as components of the invented molecules; p120 (Schreier *et al.*, 1994, *J. Biol. Chem.* 269:9090); *see also* Keinanen, K. & Laukkanen, ML. 1994, *FEBS Lett.* 346:123; Killion, JJ.  
15 & Fidler, IJ. 1994, *Immunomethods* 4:273. The compositions may be presented in unit-dose or multi-dose containers, for example in sealed ampoules and vials and to enhance stability, may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example water for injections, immediately prior to use. The sterile liquid carrier may be supplied in a separate vial or ampoule and can be a solvent or dispersion  
20 medium containing, for example, water, ethanol, polyol (*e.g.* glycerol, propylene glycol and liquid polyethylene glycol), suitable mixtures thereof, and vegetable oils. Advantageously, agents such as a local anaesthetic, preservative and buffering agents can be included in the sterile liquid carrier.

The dosage to be administered of an antibody will vary according to the particular  
25 antibody, the disease or condition involved, the subject, and the nature and severity of the disease and the physical condition of the subject, and the selected route of administration; the appropriate dosage can be readily determined by a person skilled in the art. For the treatment and/or prophylaxis of a disease or condition in humans and animals pharmaceutical compositions comprising antibodies can be administered to patients (*e.g.*,  
30 human subjects) at therapeutically or prophylactically effective dosages (*e.g.* dosages which result in tumour growth inhibition and/or tumour cell migration inhibition) using any suitable route of administration, such as injection and other routes of administration known in the art for antibody-based clinical products.

The compositions may contain from 0.1% by weight, preferably from 10-60%, or more, by weight, of the antibody of the invention, depending on the method of administration.

It will be recognized by one of skill in the art that the optimal quantity and spacing of individual dosages of an antibody of the invention will be determined by the nature and extent of the disease or condition being treated, the form, route and site of administration, and the age and condition of the particular subject being treated, and that a physician will ultimately determine appropriate dosages to be used. This dosage may be repeated as often as appropriate. If side effects develop the amount and/or frequency of the dosage can be altered or reduced, in accordance with normal clinical practice.

Figure 1 shows neutralisation of human IL-1 $\beta$  signalling with recombinant antibodies 97 and 100. Neutralization (reduction in luminescence) of IL-1 $\beta$  by increasing concentrations of antibody 97 is shown by the closed diamonds, by increasing concentrations of antibody 100 by closed squares. Controls were included: the open circle shows background luminescence, the open triangle shows luciferase production in the presence of 3pg/ml IL-1 $\beta$  alone, the open square shows luciferase production in the presence of 15pg/ml IL-1 $\beta$  alone, and the open diamond shows luciferase production in the presence of 30pg/ml IL-1 $\beta$  alone.

Preferred features of each embodiment of the invention are as for each of the other embodiments *mutatis mutandis*. All publications, including but not limited to patents and patent applications cited in this specification are herein incorporated by reference as if each individual publication were specifically and individually indicated to be incorporated by reference herein as though fully set forth.

The invention will now be described with reference to the following experimental section, which is merely illustrative and should not in any way be construed as limiting the scope of the present invention.

## **EXPERIMENTAL:**

### **Positive Selection of Antigen-Specific B cells by Flow Cytometry**

#### **30 Immunisation**

Five Sprague Dawley Rats were immunised with 10 $\mu$ g recombinant human IL-1 $\beta$  (Peprotech #200-01B) in 200 $\mu$ l, 50:50 complete Freund's adjuvant and Sterile PBS. The animals were then boosted at week 4 and week 7 with 15 $\mu$ g recombinant human IL-1 $\beta$  in 200 $\mu$ l, 50:50 incomplete Freund's adjuvant and Sterile PBS. A test bleed was taken for each

of the animals and the sera was assayed for human IL-1 $\beta$  neutralising activity (see below). The animals were then boosted a further three times at approximately 4 weekly intervals with 15 $\mu$ g recombinant human IL-1 $\beta$  in 200 $\mu$ l, 50:50 incomplete Freund's Adjuvant and Sterile PBS. Two weeks after the last boost blood and spleens were harvested.

5

*Preparation of Rat Lymphocytes and Splenocytes (the populations for enrichment)*

Lymphocytes were separated from whole blood by firstly diluting the samples at approximately 1:10 in sterile PBS. Then 8 ml of diluted blood was layered onto 5ml of Mammalian Lympholyte® (Cedarlane Laboratories Ltd. #CL5120) in 15ml Falcon tubes.

- 10 The samples were then centrifuge at 800g for 20min giving a well-defined, white lymphocyte layer at the interface between the liquids. This lymphocyte containing band and the upper 'blood plasma' containing layer were transferred into a new 15ml falcon tube and centrifuged at 800g for 10min to pellet the lymphocytes. The supernatant was collected and stored at 4°C for future use, whilst the cells were washed 3 times in immune medium (RPMI,
- 15 10% FCS, 2% HEPES, 1% Glutamine, and 1x Pen/Strep). Following the final wash the cells were frozen in 90% FCS and 10%DMSO and stored in liquid nitrogen until use.

Individual rat spleens were transferred into warmed immune media and cut into small pieces. The pieces were pushed through a mesh strainer to disperse the splenocytes. These

- 20 were pelleted by centrifugation, the supernatant was removed and the cells washed thoroughly in immune media. The cell pellets were frozen in 90% FCS and 10%DMSO aliquots and storage in liquid nitrogen until use.

*Protein G Purification of Anti-human IL-1 $\beta$  IgG from Rat Serum and Plasma*

- A pool of a total of 44ml of plasma and serum from three of the immunised rats was used to prepare an IgG fraction for labelling with Alexa Fluor 488 dye. The serum/plasma pool volume was made up to 100ml with PBS and passed through a protein G column (18ml) with a minimum contact time with the Protein G beads of 20min/ml of the pool. Following loading the column was washed with 5-10 column volumes of PBS. IgG was eluted in 0.1M glycine-HCl, pH 2.7 and neutralised using 2M Tris-HCl, pH 8.5 immediately.
- 25 30 The IgG pool was concentrated and diafiltered into PBS using an Amicon stirred cell (Millipore, Cat. No. YM1013632).

*Purification and labelling of polyclonal rat anti-human IL-1 $\beta$* 

A total of 30 $\mu$ l of 10mM Alexa Fluor 488 O-succinimide ester (Molecular Probes Inc. Product No. 20000) in dry DMSO (Perbio Science UK Ltd) was added dropwise approximately 1ml of IgG (4.5mg total) with vortexing. The reaction was allowed to 5 proceed in the dark at 37°C for 3hr. The reaction mixture was separated by application to a PD10 column (Amersham Biosciences) in PBS (the PD10 column was prepared by blocking with 20%PEG, 20000MW followed by equilibration in PBS).

*Cell Labelling*

10 An aliquot of splenocytes from the human IL-1 $\beta$  immunised rats was recovered from liquid nitrogen storage, transferred into 10ml of warmed immune media, centrifuged and washed in immune media before being transferred into a T175 tissue culture flask in 60ml immune media. The splenocytes were cultured overnight (16hr) at 37°C to deplete all adherent cell types from the cell mix. Cells that remained in suspension were counted and 15 washed thoroughly in cold PBS before use.

Cell labelling was carried out in a 15ml Falcon tube that had been blocked with blocking buffer (5%FCS, 0.1mM EDTA in PBS) on ice at 4°C for 30min. A total of approximately 3 x10<sup>7</sup> cells was incubated with 60 $\mu$ g/ml ChromPure™ rat IgG from normal rat sera (Jackson ImmunoResearch #012-000-003) and 17ng/ml human IL-1 $\beta$  (Peprotech 20 #200-01B) in blocking buffer for 1hr on ice. Following this incubation the cells were washed 3 times with 15ml ice-cold blocking buffer. After the final wash cells were resuspended in 500 $\mu$ l blocking buffer containing 2 $\mu$ g/ml purified polyclonal rat anti human IL-1 $\beta$  conjugated with Alexa Fluor 488 and 100 $\mu$ l PE-conjugated mouse anti-rat CD45RA (Serotech #MCA340PE), and incubated in the dark at 4°C for 1hr. The cells were then 25 washed 3 times with 15ml ice-cold blocking buffer. After the final wash the cells were resuspended to give a final concentration of 1x10<sup>7</sup> cells per ml in PBS containing 0.1mM EDTA. The sample was passed thought a cell filter (50 $\mu$ m Syringe Filcons BD Bioscience #340603) to remove any debris or cell aggregates that may cause an obstruction during the flow cytometry.

30

*FACS Analysis*

FACS analysis and sorting was performed using a MoFlo® Cytomation and the Cytomation Summit software. A specific population of live cells stained with PE conjugated to the anti-rat CD45RA detected in the FL2 channel, which was also positively stained for

the with FITC labelled anti-human IL-1 $\beta$  in the FL1 channel was identified. This double-labelled population represented a population enriched in B cells displaying surface IgG specific for human IL-1 $\beta$ .

##### 5 *Plating and Culture*

The enriched population of cells was seeded at 5 cells per well across 12 x 96-well tissue culture treated plates already containing a B cell stimulating culture mix. This B cell stimulating culture mix consisted of 50,000 irradiated EL4.B5 cells and 4% rabbit TSN (rabbit T cells stimulated culture supernatant) in a total volume of 200 $\mu$ l per well. The cells  
10 were then cultured for 7 days before the culture supernatant was assayed for human IL-1 $\beta$  specific antibody secretion.

##### *Screening -Primary ELISA screen*

An ELISA screen of the culture supernatant was used to identify the wells that  
15 contained B cells secreting anti-human IL-1 $\beta$  specific antibodies. The assays were carried out in 12x96-well Nunc Maxisorp plates (Fisher #DIS-971-010P) coated overnight at 4°C with 50 $\mu$ l/well of 1 $\mu$ g/ml polyclonal goat anti-human IL-1 $\beta$  in coating buffer (50mM Sodium Bicarbonate, pH 9.6). The coating buffer was removed and 50 $\mu$ l of 500ng/ml hIL-1 $\beta$  made up in PEG blocking buffer (1%PEG 20000MW, 0.1% Tween in PBS) was added to each of  
20 the wells and the plates were incubated for 1hr at room temperature. Following this incubation the wells were washed 3 times with wash buffer (PBS containing 0.1% Tween 20). The plates were then blocked with 100 $\mu$ l PEG blocking buffer for 1hr at room temperature before being washed 3 more times in wash buffer. The 40 $\mu$ l of PEG blocking buffer was added to each of the wells before adding 10 $\mu$ l of culture supernatant from the B  
25 cell culture plates. The assay was then allowed to incubate for 1hr at room temperature. The wells were then washed 3 times with wash buffer before adding 50 $\mu$ l peroxidase conjugated goat F(ab')<sub>2</sub> anti-rat IgG Fc $\gamma$  specific antibody (Jackson ImmunoResearch #112-036-071) diluted 1:3000 in PEG blocking buffer. The plates were once again incubated for 1hr at room temperature before being washed 3 times with wash buffer. Finally, 100 $\mu$ l TMB  
30 (Roche #784974) substrate was added to each of the wells and the colourless to blue colour change revealed positive wells. The plates were then read on the Multiskan (Labsystems) plate reader, using the Ascent software at 630/490 nm, for data analysis. In particular, two positive antibodies were selected for neutralising ability (see below).

*Neutralisation Assay – Biacore analysis of antibody blocking of IL-1 $\beta$ /receptor docking*

BIA (Biomolecular Interaction Analysis) was performed using a BIACore 2000 (BIACore AB). Immobilised anti-rat IgG, Fc fragment specific (Jackson ImmunoResearch) captured IgG from a 40 $\mu$ l injection of culture supernatant at a flow rate of 10 $\mu$ l/min in HBS-EP buffer. For the kinetic analysis human IL1 $\beta$  was titrated over the captured antibody at various concentrations. Results are shown in Table 1. The sensorgrams for IL-1 $\beta$  binding were double referenced by using a blocked flow cell and a buffer blank. Kinetic parameters were calculated using BIAsimulation 2.1, 3.0 or 3.1 software.

10 **Table 1**

Sample	K <sub>a</sub> e <sup>5</sup>	K <sub>d</sub> e <sup>-5</sup>	KD pM
97	3.9	3.27	83.8
100	3.61	3.05	84.5

*Specific Antibody Gene Cloning*

B cells from positive wells identified following the primary ELISA screen which 15 were specific for IL-1 $\beta$  that also showed potential neutralising activity on the Biacore screen were selected for cloning. For this step the entire contents of the well was harvested and washed in PBS before being pelleted and resuspended into 15 $\mu$ l of PBS. The cell sample was then split in 3 $\mu$ l aliquots and transferred to 0.5ml PCR tubes. cDNA was prepared by reverse transcription using a Superscript™ III Reverse Transcriptase kit (Invitrogen cat.# 20 18080-044) in a 20 $\mu$ l total volume. Primary PCR fragments were prepared by adding 2 $\mu$ l of the reverse transcription reaction and the appropriate primary primers in conjunction with a TaqPlus Precision PCR system (Stratagene cat. # 600211) in a total volume of 50 $\mu$ l as described below. A secondary PCR reaction was performed with 2 $\mu$ l of the primary PCR product, the appropriate secondary primers in conjunction with Precision PCR buffer, dNTPs 25 and TaqPlus Precision in a total volume of 50 $\mu$ l as described below.

Thermal Cycler Programs:

Reverse Transcription

- |             |            |
|-------------|------------|
| 1. 50° C    | 60 minutes |
| 30 2. 70° C | 15 minutes |

Primary PCR

1. 94° C 3 minutes
2. 94° C 30 seconds
3. 50° C 30 seconds
- 5 4. 72° C 1 minute
5. go to step 2 40 cycles total
6. 72° C 5 minutes
7. 4° C hold

**10 Secondary Nested PCR**

1. 94° C 3 minutes
2. 94° C 30 seconds
3. 55° C 30 seconds
4. 72° C 1 minute
- 15 5. go to step 2 40 cycles total
6. 72° C 5 minutes
7. 4° C hold

The PCR fragments were purified using Qiagen's Qiaquick 8 PCR purification kit (catalogue No. 28144) and eluted in 80 $\mu$ l elution buffer. The heavy chain variable fragments were digested with XhoI and HindIII and ligated into the corresponding sites of the expression vector pHFabHC (mammalian expression construct containing human  $\gamma$ 1 CH1). The kappa light chain fragments were digested with BsiWI and HindIII and ligated into the corresponding sites of expression vector pMR10-HS (mammalian expression construct containing human C $\kappa$ ). This results in the formation of heavy and light chain rat-human chimeric antibody genes. 4 x VH and 4 x VL clones (plasmid DNA from individual transformed colonies) from each cell pellet aliquot were sequenced. Consensus sequences were identified and pairs of relevant clones were used for transient expression in CHO cells.

**30 Expression in mammalian cells**

Monolayers of CHO cells in 6-well plates ( $1.2 \times 10^6$  cells/well) were transfected with 2 $\mu$ g each of heavy and light chain plasmid DNA using Invitrogen's Lipofectamine 2000 (catalogue No. 11668-019) transfection reagent according to the manufacturer's instructions. The cells were incubated for 5 days at 37°C, then the culture supernatants were harvested

and assayed for the presence of Fab, their ability to neutralize human IL-1 and their binding affinity for human IL-1 $\beta$  (Biacore analysis, as described above).

*Anti-IL-1 $\beta$  reporter gene bioassay*

5 A549 cells which had been stably transfected with the E-selectin promoter linked to the luciferase gene (hereinafter referred to as A549-ES-Luc cells) were grown in RPMI 1640 (phenol-free) containing 10%FCS, 2mM Glutamine and 1mg/ml G418. These A549-ES-Luc cells express IL-1RI receptors. Cells were plated out into white opaque 96-well plates (Packard) at 15,000 cells/well and allowed to adhere overnight at 37°C/5% CO<sub>2</sub>. Samples 10 for assay were set up in individual assay tubes, each tube containing culture supernatant (from transfected CHO cells, above) or control culture supernatant (untransfected CHO cell growth medium). Each tube additionally contained recombinant human IL-1 $\beta$  (Preprotech) at a final concentration of 30pg/ml. Tubes were incubated for 30 minutes at room temperature. A549-ES-Luc growth media was removed and replaced with 100 $\mu$ l of the room 15 temperature incubate. Cells were incubated for 4hours at 37°C in 5% CO<sub>2</sub>. Control wells that did not contain IL-1 $\beta$  were included to allow the correction for basal luciferase activity in these cells. Luciferase expression was then assayed using a luciferase reporter gene assay kit (LucLite from Packard). Figure 1 shows the results of the neutralisation of IL-1RI signalling by the transiently expressed antibodies, numbers 97 and 100. Both antibodies 20 neutralised IL-1RI signalling as shown by the loss of luciferase production with increasing antibody concentration.

## CLAIMS

1. A method of enriching a population of cells in those cells which produce an antibody that recognises an antigen of interest, comprising:

- 5      a) bringing said population into contact with an antibody that recognises a marker which is essentially unique to those cells present in the population which are capable of producing an antibody, said antibody being attached to a first fluorescent label;
- 10     b) bringing said population into contact with the antigen of interest; and
- 10     c) bringing said population into contact with a sample comprising an antibody that recognises said antigen, said antibody being attached to a second fluorescent label; and
- 15     d) separating from the population those cells which are detectable by virtue of being associated with the first and second fluorescent labels.

15    2. The method of claim 1, wherein parts a), b), and c) are performed simultaneously and the performance optionally comprises at least one wash step.

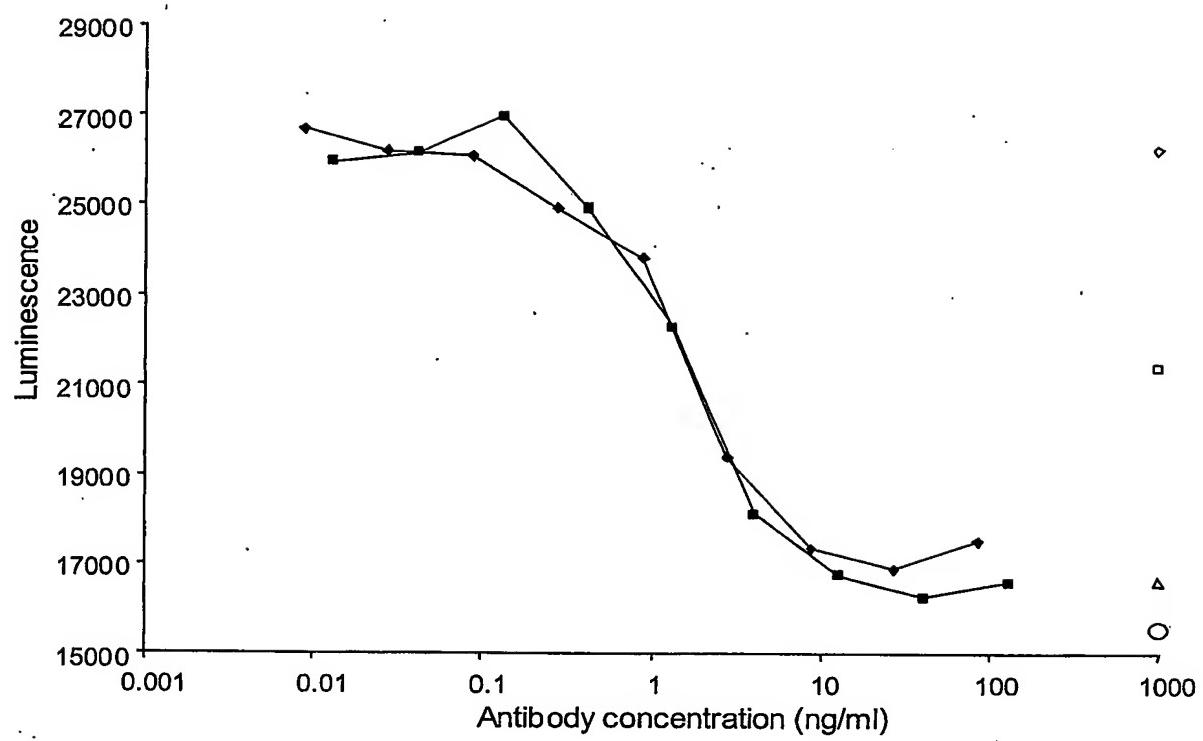

3. The method of claim 1 or 2, wherein parts a) and b), or a) and c), or b) and c), are performed simultaneously and optionally comprise at least one wash step.

20    4. The method of any one of claims 1 to 3, wherein parts a), b) and c) are performed consecutively in any order, and wherein each performance optionally comprises at least one wash step.

25    5. The method of any one of claims 1 to 4, wherein part a) additionally comprises bringing said population into contact with an antibody that recognises a second marker essentially unique to those cells present in the population which are capable of producing an antibody, said antibody being labelled with a third label.

30    6. The method of any one of claims 1 to 5, wherein the separation of the cells producing an antibody that recognises the antigen of interest is performed using fluorescence activated cell sorting.

7. A method of enriching a population of cells in those cells which produce an antibody that recognises an antigen of interest, comprising:
- a) bringing said population into contact with an antibody that recognises a marker which is essentially unique to those cells present in the population which are capable of producing an antibody, said antibody being attached to a first fluorescent label;
  - b) bringing said population into contact with the antigen of interest; and
  - c) bringing said population into contact with a sample comprising an antibody that recognises said antigen, said antibody being attached to a second fluorescent label;
  - d) separating from the population those cells which are detectable by virtue of being associated with the first and second fluorescent labels;
  - e) culturing a plurality of those cells associated with the antigen-antibody-particle complex;
  - f) screening the cultured cells to identify those cells capable of producing an antibody which recognises an antigen of interest; and
  - g) isolating said antibody directly or indirectly from the cells.
8. An antibody prepared directly or indirectly according to the method of any one of claims 1 to 7.
9. A pharmaceutical composition comprising an antibody according to claim 8 and a pharmaceutically acceptable carrier.
10. The use of an antibody according to claim 8 for the manufacture of a medicament for the treatment and/or prophylaxis of a disease or condition.
11. An antibody prepared directly or indirectly according to the method of any one of claims 1 to 7 for use in therapy.
